6. SQL Repair

SQL Repair allows you to quickly perform database repairs even when the database isn't running.

This can save you a lot of time since performing a repair of a database can take hours. In the most basic terms, repair is a process by which the database engine is used to remove or repair corruptions or other malfunctions in the database file. Using the Microsoft SQL Server Service Broker, the engine is able to use the

SQL Server client tools to access the file and use a series of fixes to bring the database back in working order. If you encounter a corrupt database file, you should run repair in order to have the database engine repair it. You can also run the repair to recover deleted data by restoring a saved version of the database or restore a backup. However, the

repair is not complete and if the repair is successful, the database will be stored offline with either the Xpress or the Compact format. The database engine uses these formats to store the databases for the purposes of crash recovery. SQL Repair

Description: SQL Repair is an application designed to repair damaged

databases or database transactions. Thanks to the usage of tools of the SQL Server client tools, a database repair can be performed on the damaged database without the need to have the database instance running. From the interface of the utility, you have the options to either preview or restore the file. In the first option,

you can preview a SQL-script file of the database itself. This can enable you to see the damage that the file has in order to use it to be repaired. In the other option, you can have the repair tool restore the database to a previously saved version. You can also fix the transaction log or just a specific part of it. In the case of a corrupted

transaction log, you can't recover the changes that you have made since the restoration. 7. SQL

for quantification of mitoxantrone in tissue homogenates: application to pharmacokinetic studies in rats.

Mitoxantrone (a doxorubicin analogue) was synthesized with the view to improving the therapeutic index of the antitumor antibiotic of the anthracenedione class, doxorubicin. It is characterized by a high

therapeutic index with little extra toxicity. Since mitoxantrone may be used to treat cancers with an anthracycline containing backbone, a validated assay method was developed to measure the drug in rat plasma and tissues. The combination of a solvent extraction procedure, normal-phase high-performance liquid

chromatography, and fluorescence detection provides detection and quantification limits of 2.5 ng/ml and 9 ng/ml, respectively. Less than 5% of the parent drug was found in tissue homogenates, except for a 20-fold decrease in liver. In contrast, homogenates of liver, lung, and brain contained between 5 and 40 ng/g of

the metabolite. The drug
